SHINGLES (herpes zoster)

What are the aims of this leaflet?

This leaflet has been written to help you understand more about shingles. It will tell you what it is, what causes it, what can be done about it, and where you can find out more about it.

What is shingles?

Shingles is a painful blistering rash caused by the same virus that causes chickenpox, known as the varicella (chickenpox) zoster (shingles) virus.

What causes shingles?

After a person has had chickenpox, the virus that caused it is still present in a dormant state in some of the nerves linked to either the spinal cord or some of the nerves of the head and neck. If the virus becomes active again, it multiplies and moves along the nerve fibres to the area of skin supplied by those nerves; shingles then appears in this area.

About 1 in 5 people who have had chickenpox will have an attack of shingles later in life.

Most attacks of shingles occur for no obvious reason, but an attack is more likely if:

- You are elderly.
- You are experiencing physical or emotional stress.
- You have an illness that weakens the immune system, such as leukaemia, a lymphoma (e.g. Hodgkin's disease), or HIV infection.
- You are taking treatments that suppress the immune system, including irradiation for cancer, chemotherapy, cortisone-like drugs, and drugs taken to prevent organ rejection.
Is shingles contagious?

Shingles is not caught from someone who has shingles, but follows an earlier attack of chickenpox. However, a person with shingles can infect someone who has never had chickenpox and/or high risk people (e.g. newborn babies, elderly people and people with reduced immunity), causing an attack of chickenpox. A person with shingles is infectious from the point of blister development up until the blisters crust over (approximately 7 days).

There is no known cause for the reactivation of the varicella zoster virus; if a person with a weakened immune system comes in contact with a person with chickenpox, it may reactivate it and the patient will have shingles.

Is shingles hereditary?

No.

What are the symptoms of shingles?

Pain is usually the first and most predominant symptom of shingles. However, it is important to note that not all people with shingles will experience pain; for example, many young people will not experience any pain, but rather just an itching or mild burning sensation of the affected area.

For those who do experience pain, this pain is usually localised and can range from mild to severe; a constant dull, tingling, aching or burning pain/sensation may be experienced. The rash usually appears a day or two after these symptoms, and a fever and/or a headache may develop.

What does shingles look like?

The first sign is the appearance of groups of red spots on a pink-red background, which quickly turn into small fluid-filled blisters. Some of the blisters burst, others fill up with blood or pus. The area then slowly dries out, and crusts and scabs form. The scabs will drop off over the next 2-3 weeks.

The rash usually covers a well-defined area of skin on one side of the body only, without crossing the midline to the other side. Its position and shape will depend on which nerves are involved. Shingles can affect any area, but common patterns include a band running round one side of the chest, or down an arm or leg. Sometimes pale or dark scars follow shingles, particularly after a severe attack. Less commonly it can affect the face, around one of the eyes, in which case complications in the eyes can occur.
A chickenpox-like rash occasionally comes up at the same time as shingles. This may indicate a more serious and widespread attack of shingles or that there is an underlying reason for the shingles.

**How is shingles diagnosed?**

Early in the course of shingles, before the rash is present, it may be difficult to make the diagnosis. Later on the diagnosis is usually straightforward, based on the story of pain appearing before the rash, and on the typical appearance of the rash.

If there is doubt about the diagnosis, scrapings may be taken from a blister, by your doctor or dermatologist, and looked at under a microscope.

**Can shingles be cured?**

Shingles usually resolves on its own within a few weeks. Oral medication can make the rash of shingles clear sooner and can reduce its unpleasant effects.

These effects depend largely on which nerve is involved:

- Shingles of the area served by the nerve that carries sensation from the front of the eye can lead to inflammation and ulceration of the eye structures, and later to scarring, glaucoma and/or blindness. Blisters coming up on the side of the nose will alert your doctor to this risk, and you should also get urgent advice from an eye specialist (ophthalmologist).
- Muscles supplied by the nerves taking part in the shingles occasionally become weak, for example, temporary facial paralysis of the affected side.

The pain of shingles may persist long after the rash has cleared (this is called *postherpetic neuralgia*), particularly in the elderly. Usually this goes away within 6 months, but a few people can experience pain for a year or more.

**How can shingles be treated?**

- *To shorten the attack.* Antiviral drugs, such as acyclovir tablets and/or cream, are safe and can do this, but only if they are given within the first few days of an attack.
- *To make it less painful.* Rest and taking pain-killers may help.
- **To deal with complications.** A bacterial infection complicating shingles may require an antibiotic cream or tablets. Eye involvement will need a specialist ophthalmic review, and eye drops may be prescribed.
- **To prevent postherpetic neuralgia.** Taking antiviral drugs during an attack of shingles may reduce the risk of getting postherpetic neuralgia, and can shorten its duration if it does occur.
- **To treat the pain of postherpetic neuralgia.** Using an anaesthetic ointment (lidocaine 5%) before applying a topical analgesic cream (capsaicin cream) may help. The lidocaine can be bought over the counter, but the capsaicine needs to be prescribed by your doctor. Treatments that are sometimes also used include antidepressants, and anticonvulsants, as well as pain killers, such as non-steroidal anti-inflammatories; all of these treatments should be prescribed by your doctor, and will depend on each individual case.
- The live varicella–zoster vaccines are licensed for immunisation against chickenpox in high risk people. They are not recommended for routine use in children. Rarely, the varicella–zoster vaccine virus has been transmitted from the vaccinated individual to close contacts.

**Self help (What can I do?)**

- High risk people such as newborn babies, elderly people, people with reduced immunity, and those who have not previously had chickenpox (especially pregnant women) should avoid contact with shingles until the blisters crust over.
- See your doctor as early as possible if you think you have shingles, particularly of the face, as antiviral treatment works best if taken early in an attack.
- You may need to take time off work initially, however you can return to work once the rash has dried out and crusted over.

**Where can I get more information about shingles?**
